QRR#3
INTERNATIONAL DISASTER ASSISTANCE IN THE MEXICO CITY EARTHQUAKE

Louise K. Comfort

1986

Quick Response Research Report #03
The Decision Making Process in International Disaster Assistance

Immediately following the first news announcements of the 19 September 1985 earthquake in Mexico City, disaster assistance from international sources began arriving in Mexico City. Food, medical supplies, heavy equipment, clothing and other goods began arriving by the ton at Mexico City International Airport, much of it unrequested; most of it untargeted, with no designated recipient organization or group. Simultaneously, international rescue workers at the sites of collapsed buildings in Mexico City were hampered by inadequate knowledge of the locale, lack of appropriate equipment and lack of coordination among the multiple rescue teams and organizations. Equipment, supplies, rescue workers and money arrived from fifty-two nations and four international organizations to assist the disaster relief effort in Mexico City. The Government of Mexico established an expert commission made up of distinguished officials and highly respected citizens to implement valid procedures for cataloguing and tracking the disposition of incoming supplies. The decision-making tasks involved in coordinating the international assistance efforts and matching them to actual local needs were enormously complex.

The massive earthquake prompted an extraordinary outpouring
of humanitarian international assistance to the Mexican people in their tragedy. But questions remain. What kinds of assistance, and how much, were actually needed by the Mexicans? What are the most appropriate means of getting aid to the Mexican victims of the disaster? In what ways can international organizations, operating in concert, take constructive action to assist another nation struck by tragedy?

Clearly the international community acted promptly, warmly and generously in response to perceived needs created by the disaster in Mexico. The Mexican Government, in turn, acted responsibly to set up disaster operations procedures to manage the rescue and relief efforts, and the Mexican people acknowledged gratefully the care and concern showed them by the international community. Yet, despite the good will, effort and energy expended by international and Mexican participants, the actual results of international rescue and relief operations had a relatively minor effect in lessening the toll of dead and injured, restoring functional services to the city or easing the burden of those people rendered homeless due to the earthquake. The comparatively weak ratio of results achieved to assistance extended compels a reconsideration of the international disaster assistance process.

In Mexico City, the enormity of the need was obvious to all who watched the evening news. The availability of resources -- time, skill and materials -- was equally clear, documented by passenger lists and shipping labels on incoming planes and by
thousands of volunteers who helped to clear debris, direct traffic and distribute food and water to those made suddenly homeless. The problem, however, was the complex one of making timely and appropriate decisions simultaneously under conditions of great uncertainty and incomplete information. The inability of rational modes of problem solving to cope with great complexity, noted by other researchers, was painfully apparent in light of the enormity of demands engendered by the earthquake disaster. The sobering question raised by the events in Mexico City is whether members of the international community will use this opportunity to reflect upon means by which they might improve their shared decision-making process to achieve a stronger ratio of results produced for efforts extended in international disaster assistance.

The Logic of Action in Uncertain Environments

Searching for an explanation of the decision making process in international disaster assistance, one quickly dismisses the thesis of events proceeding according to a rational plan. The degree of error, confusion, uncertainty or omission that characterized the daily operations of the international relief agencies during the first weeks following the earthquakes defied the dedicated efforts of the most professional personnel in international organizations to order their actions in optimal ways. Yet, decisions were made; actions were taken, and as the hours and days of disaster assistance activities proceeded, an increasing degree of order and rationality evolved from the
interaction of participating organizations.\textsuperscript{10}

Among the international search dog teams, for example, the initial frustration of not knowing which buildings had been searched or what buildings offered the most likely chance of finding victims alive, the wasted time involved in waiting for needed equipment to move debris, once survivors had been located; the unwitting clash of technologies involved in the disruption of silence required for seismic detection of survivors by the noise of traffic and other rescue vehicles compelled the various teams to re-examine their procedures of operation.\textsuperscript{11}

Clearly the members of the various international teams arrived in Mexico City with no predesigned plan for their rescue activities. They separately engaged in rescue operations, according to their respective forms of training and experience. Encountering difficulties and frustration apparent in the lack of coordination among their particular efforts to accomplish their shared goal, members of the teams devised their own procedures for coordinating their interdependent activities in a more effective manner.\textsuperscript{12}

These conditions suggest a different mode of rationality in operation than the standard administrative model of rational planning, in which one first devises a plan for action in regard to a specific problem, then systematically carries out the plan to achieve the desired result.\textsuperscript{13} Instead, organizations acted simultaneously in response to a particular problem. Then, observing the results against the shared goal of rescuing
survivors, they redesigned their respective actions to approximate that goal more closely. The evolving degree of cooperation between the individual organizations resulted in more effective performance for the set of international organizations engaged in search and rescue activities. It is a logic of action, reflection upon the consequences of that action, and choice based upon fit performance. The decision-making process, employing rationality, is similar to the biological model of evolutionary choice, which assumes adaptation in response to the demands from the environment, with adaptive choices made upon the basis of fitness in that environment. Characteristics of this model have been recognized in the decision-making processes of business organizations also operating in environments of great uncertainty and complexity.

The Evolutionary Model of Adaptation in Organizational Choice

What is the model of evolutionary adaptation in complex environmental conditions and in what ways, if any, does this model offer insight into the decision-making process in international disaster assistance? The concept of adaptation is used by biologists to explain the processes whereby "an initially unorganized system acquires increasing self-control in complex environments." Examining the process of adaptation in both natural and artificial systems, Holland states that

adaptation, whatever its context, involves a progressive modification of some structure or structures. These structures constitute the grist of the adaptive process, being largely determined by the field of study.
The structures undergoing modification display the visible evidence of adaptation, but successive structural modifications are likely to reveal a basic set of operators that act upon the structures. It is the repeated action of these operators upon the identified structures that produces the observed adaptation.19

The model of adaptation is simple. There are three major components in the process that can be identified for any field. First, there is the environment of the system that is undergoing adaptation. The environment provides the context in which adaptation occurs and offers multiple stimuli and obstacles to the process. Second, the 'adaptive plan' is the set of beliefs or conditions influencing structural choices in the environment at successive stages of development in order to improve performance. The adaptive plan includes the central values and intelligent sensing mechanisms that drive the selection process. Third, 'the measure of performance or 'fitness' of the structure in that environment serves as the criterion for choice in retaining or modifying the structures.

These components interact with one another in an adaptation process that can be characterized by a set of fundamental questions appropriate to any system. These questions, posed by Holland, are as follows:

1. To what parts of the environment is the system adapting?
2. How does the environment act upon the adapting system?
3. What structures are undergoing adaptation?
4. What are the mechanisms of adaptations?

5. What part of the history of its interaction with the environment does the organism retain?

6. What limits are there to the adaptive process?

7. How are different adaptive processes to be compared?20

Each of the questions identifies a basic characteristic of the adaptation process. These characteristics, defined as elements for a particular adaptive process, can be represented by symbols which may be used to model the process mathematically. Since the purpose of this essay is not to develop a mathematical model but to identify, if possible, an explanatory model for the international disaster assistance process in Mexico City, these characteristics will be defined in common language terms. Corresponding to the seven questions listed above, the terms are defined as follows:

1. Environment (E): the specific parts of the larger environment or universe to which the system under study is adapting.

2. Inputs (I): the range of signals transmitted from the environment to the system undergoing adaptation.

3. Structures (S): the set of attainable forms within which the adapting plan acts in the environment.

4. Operators (O): the set of means or processes for modifying structures employed by an adaptive plan.

5. Memory (M): the specific aspects of the history of its interaction with the environment that the adapting system retains.

6. Limits (L): the existing constraints to the adaptive process.

7. Criterion (C): the measure by which different adaptive processes may be compared to determine fitness within the set.21
Using the terms defined above, the adaptive process may be represented by the schema shown in Figure 1. The general environment generates stimuli that activate an adapting system. This system is illustrated by the presence of an adaptive plan that receives inputs from the general environment. The adaptive plan then selects operators that, in turn, act upon structures located in a particular environment. This action produces a performance in the particular environment that is observed and evaluated according to the criterion of fitness. Feedback from the performance is returned to the adaptive plan which retains in its memory a selective record of the event. Informed by the previous experience, the adaptive plan initiates a new cycle of adaptation, seeking to improve its performance within the limits of the operating environment. The process is dynamic.

While the schema depicts the form and flow of the adaptive process, it is equally important to note the major obstacles to adaptation. These obstacles, according to Holland, are also generic, and inhibit adaptation in any environment. They are: 1) size; 2) complexity; 3) interdependence among parameters; 4) variance in performance measures over time and space; and 5) the great flux of information from the environment that needs to be screened and ordered in terms of relevance.22

The adaptation process depicted by this model is a very simple dynamic of selection for action, trial, observation of performance and new selection on the basis of a fitness criterion. It assumes intelligent actors that utilize information from observed performance as their basis of choice in
successive actions. It acknowledges simultaneous actions by multiple operators, yet sorts the effects of those actions into categories for second stage development on the basis of performance. To what extent is this model applicable to the international disaster assistance process? If appropriate, the model may be used to explain the events in Mexico City following the 19 September 1985 earthquake.
The International Disaster Assistance Process in Response to the
19 September 1985 Mexican Earthquake

The context and sequence of events following the massive 1985 earthquake in Mexico City offer an apt environment in which to observe the continuing search for order and an evolving pattern of improved performance among multiple organizations. The domain of possible adaptive processes is vast. This analysis will select two particular environments out of the very large set of possible environments encompassing international disaster assistance to observe the interaction among the component elements of the model in order to determine whether adaptive processes were operating to improve performance. These environments, containing some common and some unique elements, illustrate central problems in the international disaster assistance process.

First, the environment of search and rescue operations, carried out by international rescue teams will be reviewed to determine whether an operating logic of action emerged from the conditions of complexity and uncertainty surrounding this process. This phase of international disaster assistance is selected for analysis for several reasons. The President of Mexico, Miguel de la Madrid Hurtado, declared the first priority for the Mexican government and its people to be search and rescue of survivors trapped in the damaged buildings.23 Further, international teams generated a high level of visibility and attention in the media with their applications of new
technologies, never before used in disaster operations, to the tasks of search and rescue. Due to high visibility and vital to retrospective analysis, activities of the international search and rescue teams were documented carefully by multiple agencies, allowing consideration of the same events from multiple perspectives and various sources of evidence. Finally, several significant research studies have reported an 'emergent' cooperation among multiple organizations engaged in disaster response, especially in search and rescue operations. This analysis builds upon findings reported in previous research in its theoretical conception of patterns of organization emerging from the complex environment of disaster.

Second, the perceived effect of international disaster assistance efforts, including the search and rescue operations, will be reported from a survey of residents of the damaged neighborhoods in Mexico City. The actual delivery of international disaster assistance to the damaged neighborhoods, reported through the perceptions of residents, offers a valuable check on the portrayal of the process through media reports, official documents or interviews with participants or governmental decision-makers. These two particular environments of the international disaster assistance process both complement and contradict one another. To the extent that contradictions are reduced and complementarity increased over successive stages of interaction between the two sub-sets, the evolution of 'fitness' or improved performance in the larger environment of
international disaster assistance is indicated.

Adaptation in Performance of International Teams Engaged in Search and Rescue Operations following the 19 September 1985 Mexican Earthquake

Using the model of adaptation outlined above, it is possible to identify the different components of an adaptive process from the context of post-disaster search and rescue operations in Mexico City. The environment under analysis includes the domain of international actors only, for although the international teams interacted regularly with the Mexican government and sub-units of the Mexican government in search and rescue operations, the focus of this study is the international disaster assistance process and its performance in the context of the Mexican disaster. The impact of the international teams upon the operations of the Mexican government in search and rescue activities likely generated a separate adaptive process, but consideration of that process is beyond the scope of this study. The specific environment of the international search and rescue teams generated multiple stimuli and powerful obstacles to effective performance in international disaster assistance. These stimuli and obstacles will be described in the identification of terms for the adaptation model in this context.

The second major component of the model is the 'adaptive plan' or the set of inputs from the environment interacting with possible forms for action that determine the actual choices made in international search and rescue operations. The adaptive plan
in this environment includes the shared values of humanitarian concern for victims of the disaster and commitment to responsible action demonstrated by all nations that extended disaster assistance to Mexico. It is expressed, for example, in the logo of the U.S. Search and Rescue (SAR) Dog Team, "That Others May Live".27 Again, the specific elements of the adaptive plan will be described in the identification of terms for the model.

Finally, the criterion of fit performance in this environment was the rescue of human life, drawing upon professional standards of organizational effectiveness and efficiency that were acknowledged by the international rescue teams, separately and collectively.28

Given the initial assessment that the basic components of an adaptive process did exist in the Mexican disaster, the further elements of the model can be specified. These elements will be defined in reference to seven fundamental terms characterizing the adaptation process.

Environment

The system under study is the decision-making process in international disaster assistance. The system itself is nascent, and although decisions are clearly made regarding the allocation and implementation of international disaster assistance, the process by which these decisions are made and the criteria for choice appear to be evolving with experience in disaster operations. The larger environment for this system is disaster management in catastrophic natural or technological events. More
specifically the tentative system of decision making that emerged among international organizations extending disaster assistance following the earthquake was adapting to the wider disaster environment in Mexico City. The time period under study is the twelve-day period from 19 September through 1 October 1985 during which the international search and rescue activities occurred. Particular characteristics of this environment include the urban setting of 18 million people, the entrapment of large numbers of people in collapsed multistory buildings, and the technical difficulties of rescue operations that required moving or cutting through vast amounts of concrete and steel debris.

Inputs

Multiple stimuli from this environment acted upon the decision making process in international disaster assistance. Three types of stimuli, however, were powerful and consistent influences upon the system, engaging its attention and prompting its response. First, the media, and particularly the international press, acted very quickly to transmit news of the earthquake to national capitols of the world. Second, news of the catastrophic earthquake prompted an immediate and generous humanitarian response in disaster assistance from nations around the world. At final count, fifty-two nations and four international organizations sent personnel, equipment, materials and money to assist Mexico in the disaster rescue and recovery operations. The actual arrival of these personnel and goods in Mexico both increased the possibilities and altered the
requirements for productive action in the disaster environment. Third, direct observations of participants in search and rescue activities contributed a continuing flow of information and assessment of requirements for effective action. Equally, reports and response of informed observers regarding the unfolding search and rescue operations added an important perspective to the decision-making process. All three inputs contribute to the transmission of data to multiple recipients simultaneously and the transformation of those data into information marshaled for decision support through the common filter of the goal for disaster operations, saving lives and assisting those injured, made homeless or otherwise affected by the disaster.

**Structures**

Again, multiple structures emerged in the activities of the search and rescue operations process. The clearest and most visible structures, were, first, the search and rescue teams sent by nine nations -- France, West Germany, Israel, Italy, Spain, Switzerland, United Kingdom, United States and Venezuela. Not all teams were in communication with one another; not all teams had the same technologies or strategies in search and rescue operations. Yet, all teams did share the same commitment to locate and rescue victims trapped in the debris. Second, the national embassies located in Mexico City served as points of communication between the respective search teams and their national capitols and as possible points of coordination among
the teams working in the field. Third, the international organizations -- the United Nations Disaster Relief Office, the International Red Cross, the Pan American Health Organization and the Catholic Relief Services, to name a few of the most visible and/or most active -- offered possibilities for potential collaboration among national efforts in collective disaster operations. Each set of structures engaged in disaster operations and, in so doing, had the opportunity to either facilitate or obstruct the performance of the overall international disaster assistance process.

Operators

The means of adaptation in the international disaster assistance system are primarily those involving communication -- patterns, styles, technologies and language. Since the process of adaptation in this environment of disaster depends upon the capacity of the human participants to learn from their own, and others', experience, the form, content and mode of communication among them becomes the primary set of operators upon the structures named above. Specifically, this set of operators includes the informal patterns of communication that developed between search team members and between the different participating teams. It also includes the more formal patterns of communication that took place between their respective governments through the medium of embassy contacts. Further, it includes the limited but potentially important contacts between the national embassies and the international disaster relief
organizations. Finally, it includes the very limited, but potentially even more powerful contact between the set of structures -- field search teams, national embassies and international organizations -- and the citizens of Mexico who actually received some benefit through the international disaster assistance process.

Memory

The interaction among operators and structures in the given disaster environment is extremely complex. Not all of those interactions are retained in the collective history of the process. Memory constitutes the vital record of those events and experiences 'selected' as critical to performance. These, then serve as the lessons learned from the interaction. Several types of experience were vividly embedded in the collective memory of the human participants in search and rescue operations. First was the great sense of frustration at not being able to accomplish their intended goals because of lack of coordination, organization or facilitation among the separate actors in the process. This sense of frustration was heightened by the recognition that intent, materials or personnel were not lacking; rather, communication, planning and administrative skills appropriate to the magnitude of the task were.35

Second, equally powerful in shaping the collective memory of this process was the shared experience of experimentation with new methods of developing coordination, inventing communications procedures between participants and pooling information regarding
common tasks. Finally, the ensuing satisfaction of improving performance through cooperation provided an important link between past and future performance. It left with each participant the glimpse of effectiveness in collective performance and the generative commitment to increase this effectiveness in further interactions. Memory serves as the stored body of knowledge derived from experience that has been judged worthy of retention in guiding the decision process.

**Limits**

Limits to action abound in disaster operations, and a primary one is the sheer complexity of a disaster the magnitude of the Mexican earthquake. The vastness of the search and rescue task, involving some 954 collapsed buildings with estimated tens of thousands of people trapped in them, presented the search and rescue teams with an extraordinarily difficult problem for action. Compounding the complexity was the urgency of time. The chances of rescuing survivors alive from the debris declined with each hour, each day of delay in search and rescue operations. The technologies employed in the search and rescue operations introduced new possibilities for action, but added new requirements for field support, information and coordination. Unplanned, these requirements at times had the perverse effect of delaying rather than facilitating the search and rescue operations.

A third, and powerful, limit on the decision-making process in international disaster assistance was availability and
accessibility to accurate, timely and relevant information. This condition was exacerbated by the severe damage to Telefonos de Mexico (TELMEX), the Mexican telecommunications facilities, that virtually closed down all international telephone communications in the first ten days after the disaster.\textsuperscript{39} Without ready and easy access to authorities in Mexico, it was extremely difficult for decision-makers engaged in the international disaster assistance process to confirm reports of damage, correct errors in perception and make appropriate allocations of personnel, equipment and materials to facilitate disaster operations.

Fourth, the diversity of languages, technologies and premises for operation among the different units and levels of decision makers in the international disaster assistance process constituted a significant limit on the capacity of the participants to attain a common understanding of their shared responsibilities. The unfortunate experience of witnessing the disagreement between the French and the U.S. search teams over the most appropriate procedure to use in locating survivors in unsafe buildings illustrates the obstacles encountered in the decision-making process.\textsuperscript{40}

Finally, the limiting conditions of complexity, time, information and communications interacted with one another to compound the obstacles confronting human decision makers in the search and rescue process. The dynamics of the process itself, uncharted and little understood by the participants, served to limit their capacity for effective performance.
Criterion for Fit Performance

The final element in the model of adaptation in international search and rescue operations is at once the simplest and the most important. It is the criterion for choice regarding which actions are repeated and which actions are discarded in the continuing search for fit performance. It represents the logic of action under uncertain conditions and, very simply, can be defined as "what works" in widely varying circumstances, judged by highly diverse actors. Agreement on "what works" is based largely upon the contribution of a given action to achieving the common goal. In search and rescue operations, this measure of performance was the location and rescue of live victims. In the larger case of the Mexican disaster, this goal was also very clear and very simple to all involved -- it meant actions to save lives, assist the homeless and restore basic services. These goals were recognized in the priorities for action set by President Miguel de la Madrid of Mexico and acknowledged by all participating international teams.

A second element that further specified the criterion for fit performance was the shared recognition of professional standards by the participating teams. Although the members differed in language, culture and technology, they respected the training, discipline and accomplished performance of their international colleagues. A common sense of professional standards informed their separate judgments of fit performance.
The Model of Adaptation in International Disaster Assistance

The seven elements identified above -- environment, inputs, structures, operators, memory, limits and criterion for fitness -- present the components of a possible model of adaptation in the decision making process in international search and rescue operations in the Mexican earthquake disaster. To Holland, a problem in adaptation is recognizable when the limits, environment and criterion of fit performance can be specified within a given context. An adaptive system is identifiable when the structures, operators, inputs and adaptive plan can be specified within that context.43 This inquiry will review a selected sequence of events in search and rescue operations in the Mexican disaster to determine whether adaptation, or an evolutionary improvement in performance, did in fact occur.

The Evolution of Improved Performance in International Search and Rescue Operations

Applying this model of adaptation to international search and rescue operations, it is possible to distinguish four phases in the decision-making process that illustrate beginning steps in the evolution of improved performance. These phases indicate both increasing control over the environment of search and rescue operations by individual search teams as well as increasing recognition of shared objectives and merit of collaborative efforts among the international teams. The process is indeed complex, and it will be described here only in sufficient detail to indicate the operation of the model.
Initial Decision to Send Search and Rescue Teams to Mexico City

The wider environment in which decisions were taken by national governments to send search and rescue teams to Mexico City was characterized by very little information and great uncertainty. The process also differed from nation to nation. In the interest of brevity, the U.S. case will be used to illustrate the dynamics of the process. While the details differed, similar conditions existed for all countries that sent search and rescue teams.

The particular environment in which the United States made the decision to send search and rescue teams to Mexico City was one of classic disorder in the midst of enormous complexity. The first news reports of the disaster in Mexico City had greatly exaggerated the damage, estimating that 37% of the city had been destroyed with possibly 100,000 dead. Further confirmation or correction of these reports was not possible, because international telephone communications had been destroyed. In Mexico City, the U.S. Ambassador contacted officials of the Mexican government to offer assistance. The Mexican officials replied that they were in the process of determining what kinds of assistance were needed. In Nashville, Tennessee, trained search and rescue personnel attending the annual conference of the National Association of Search and Rescue (NASAR) learned of the Mexican disaster through televised news reports and immediately contacted U.S. officials in the State Department,
volunteering their assistance in disaster operations.45 Hours passed with no further information from Mexico City or Washington. News reports stated that President Miguel de la Madrid of Mexico had announced that Mexico would be able to manage the disaster with her own resources.46

Aware that every hour of delay reduced the likelihood of finding live victims in the debris, trained NASAR personnel in Nashville worried about the status of search and rescue operations in Mexico City and waited for a response to their offer of assistance. Finally, the telephone call came from Washington, late on Friday, September 20, 1986, confirming a request from Mexican officials for experts in mine safety, demolition and search and rescue operations. The U.S. would send a team of 11 personnel with specialized equipment and search dogs to Mexico City to assist in search and rescue operations. Members of the team were asked to be ready to leave early on Saturday morning, September 21, 1985. The team of seismic detection experts, snake video camera experts, mine safety experts and trained search dogs with their handlers arrived in Mexico City at 3:00 p.m. local time, Saturday, September 21, 1985, nearly 56 hours after the earthquake had occurred.47 Additional personnel arrived later, bringing the total number of U.S. personnel involved in search and rescue operations to 27 members, organized in six teams.

In this environment of unplanned, unfolding events, a problem for adaptation is clearly recognizable. The limits for
action in disaster search and rescue are time, information, and the enormous difficulty of the task. The environment of nearly 1000 collapsed buildings with estimated tens of thousands of persons trapped inside compelled a reconsideration of routine operations. The criterion for fit performance was the rescue of survivors.

From this context and the reported sequence of events, an adaptive system is also identifiable. The structures through which adaptation to demands from the environment was occurring were the international search and rescue teams. The operators modifying these structures were the means of communication among the different participants: among members of the separate international teams; between the separate teams and their respective governments; between the national embassies and the Mexican government officials. The inputs to the adaptive system were, most importantly, the international press, and the various media correspondents who reported the events and consequences of the disaster to their respective national capitals. The adaptive plan is demonstrated through the concurrent decisions by nine nations, influenced by information from the disaster environment and awareness of actual skills, technologies and personnel available in their respective nations, to mobilize and send search and rescue teams to Mexico City.

The linkage is tenuous; the messages communicated incomplete and at times contradictory. Errors were made; yet, they were corrected and constructive actions were taken on the basis of
additional information. For example, the initial judgment of the Mexican government not to request assistance was changed on the basis of further evidence, and the next set of actions involved in actually sending the U.S. team followed accordingly. The most powerful recollection of this history of interactions stored in the collective memory of search and rescue personnel was the number of hours (56) subtracted from the optimal period (72 hours) for life-saving search and rescue operations immediately following the disaster, due to lack of clarity and order in the decision-making process.

Allocation of Tasks in Search and Rescue Operations in Mexico City

Once in Mexico City, the U.S. search team reported to the U.S. Embassy for guidance in field operations. The U.S. search team was to work under the supervision of the U.S. Embassy in the central section of the city where disaster operations were being directed by the Mexican Navy department of Marine. The actual extent of administrative support and guidance available to the search team, however, was extremely limited. The U.S. Embassy did provide translators to the search teams, and the translators, rather than any coordinating administrative personnel, directed the search teams to the locations where victims were presumed alive.48

The initial experience of the U.S. team in field operations was extremely frustrating. Needed supplies and trained personnel to support the field teams were not available. For example, the
dog teams had no means of communicating between field sites and the Embassy's disaster operating center, greatly hampering their work when additional equipment or medical assistance was needed. The lack of hand-held radios, essential to disaster operations, delayed by minutes and hours the coordination of equipment and personnel necessary to rescue operations. The TV camera team had a radio supplied by the Embassy, but lack of trained communications personnel at the Embassy made it difficult to send or receive information. Under conditions where time means life, the lack of adequate communications facilities between participating groups and organizations proved seriously limiting to effective performance in search and rescue operations. The problem was partially solved, days into the rescue operations, when an Embassy employee discovered a long-forgotten box of hand-held radios in the Embassy basement and wondered if they might be useful in the disaster operations.49

Differing technologies and techniques of rescue operations conflicted in field operations. The sensitive seismic detection equipment employed by the group of experts from the U.S. Office of Mine Health and Safety required silence for effective operation. Yet, stopping the jackhammers and cutting saws of the other rescue teams to allow the seismic team to work would delay the possible rescue of other victims. Recognizing the dilemma, members of the teams using different types of equipment conferred and agreed to schedule their work so that the seismic team would work at night when it was quiet to identify possible leads for...
live victims. These leads would then be followed up by the teams that could cut through the debris to reach survivors during daylight hours. These incidents and others compelled the members of the U.S. team to re-examine their operating conditions and procedures.

Several steps were taken to improve performance in the field. One of the members of the U.S. team, experienced in emergency management operations, established a separate office in the U.S. Embassy to provide administrative support specifically to the U.S. dog teams, but also provided information and coordination to other U.S. experts in the field. During the day, the administrative coordinator would meet with Mexican government officials, secure maps of the damaged areas with building sites marked that were known to have people trapped inside, check the status of these buildings for current information regarding signs of life, identify the types of structural damage to the building and the supposed location of the survivors to assess the likely types of equipment necessary for rescue operations, and assign the teams accordingly for maximum utilization of time and skills.

A problem for adaptation was clearly apparent in the operation of the U.S. search teams in Mexico. The limits to their actions were the very real constraints of time, lack of coordination, lack of communication facilities and lack of systematic information. The environment was chaotic in terms of administrative operations, difficult and risky in terms of the
work setting among collapsed buildings in an unfamiliar city. The criterion for performance was obvious to all participants. What mattered was the successful discovery and rescue of human life from the debris. Aware of the obstacles that hindered their efforts at search and rescue, members of the U.S. team re-examined their activities within this environment in order to improve their performance, given the relentless limits of time and complexity.

An adaptive system is also identifiable in this sequence of events. The structures engaged in operations were the sub-groups with differing skills and using different technologies of the U.S. team -- the dog teams, the seismic team, the video camera team and the mine safety experts. The operators that modified the performance of these structures were the informal patterns of communication that developed among the members of the U.S. team, as they met in the evenings in their hotel to share information about the day's activities and to receive information regarding the next day's assignments. The inputs to the adapting system were the direct observations of the individual team members and the reports from relevant organizations or Mexican citizens that were collected and summarized for members of the team through the evolving operations center (Dog Base) established after arrival. The adaptive plan is revealed through the interaction of these inputs from the environment through the communications processes with the acting structures, the search and rescue teams. Again, the criterion for fit performance drives the growing awareness of
the need to change the operating procedures and organizational structure of search and rescue operations. The adaptive plan represents the learning capacity of the individual participants engaged in search and rescue operations, as they assimilated information from their environment, used that information to guide their own choices for action, given the resources, constraints and operating forms available.

A vital element stored in the collective memory of the U.S. search team regarding these interactions is the significant improvement they were able to achieve in their performance in the field with systematic collection of information regarding the operations sites, readily available and accessible communications between field and administrative operations and appropriate allocation of tasks and technologies among the different members and groups of the search and rescue team. Equally apparent, however, was the fact that the obstacles to effective performance encountered by the U.S. team were also hindering the operations of other national teams engaged in the international search and rescue process.

Coordination Among the International Search and Rescue Teams

Given the lack of coordination, information and communication among the different national teams engaged in search and rescue operations, it is not surprising that conflicts would emerge over differing technologies and different approaches to reach the same objective -- the location and rescue of live victims. Participation in rescue activities surfaced the
dilemmas involved in the process and resulted in differing judgments about appropriate technical and administrative requirements to support international search and rescue operations. Several incidents illustrate these dilemmas.

At Juarez Hospital, dangerously unsafe structurally but with known victims trapped in the debris, the French and the U.S. rescue teams working in different areas of the same site sharply disagreed over the most appropriate means of reaching the victims. The U.S. team, mindful that each hour of delay reduced the chances of getting the victims out alive, advocated the use of heavy equipment to clear access to the victims more quickly. The French team, mindful of the risk of the unsafe building collapsing altogether and crushing the victims in the process, favored a slower, tunneling approach that might delay the rescue but be less likely to precipitate further structural collapse of the building. Unable to resolve the dispute, the French team left the site and left Mexico City the next day.53

A similar dilemma emerged in the use of British military helicopters in the rescue operations. The collapse of multi-storied buildings required the removal of heavy concrete and steel sections of debris to reach the victims underneath. One means of accomplishing this task was to use helicopters that had the capacity to lift heavy objects. The British had military helicopters with this capacity stationed in Belize, only a few hours away. The request came from the Mexican government to the British Embassy for the use of those helicopters. The British
operations officer in the Embassy made the arrangements for sending the helicopters with experienced technical crews to Mexico City to assist in the rescue operations. Disagreement over the appropriate rescue techniques among the various rescue teams emerged, and the use of British helicopters was criticized because the powerful machines would be too noisy and disturbing to the other rescue efforts. The request came to cancel the dispatch of the helicopters to Mexico City. The British Embassy complied. Hours later, the request came again for the use of the helicopters. The British Embassy renewed the arrangements to send the helicopters to Mexico City. They arrived the next day, and were sent to a site outside the city. The crews were advised to await further instruction for their use. Three days later, the helicopters and their crews returned to Belize, never having participated in the rescue operations. The conflicting views and indecision over the appropriate use of differing technologies in the rescue operations illustrate the extent of uncertainty, complexity and differing perceptions of the same problem among the multiple participants in the international search and rescue process.

Awareness of the cost of lack of coordination and communication among the different international teams was expressed by representatives of several of the participating teams. The head of the German rescue delegation noted both the lack of communication between central operations and field operations and the organizational problems in performance due to
a lack of adequate preparation for disaster operations by the international rescue teams. The leader of the French rescue delegation acknowledged the same general lack of organization and plan for action. Members of the U.S. delegation also confirmed this observation. While these spokesmen recognized the tremendous effort, generous good will and professional skills that individual international teams displayed in the rescue effort, they also acknowledged the frustrating delays and heartbreaking loss of vital rescue time due to the lack of information, coordination and necessary reciprocal support among the participating teams.

The problem in adaptation in this sequence of interactions is defined by the limit common to all international teams—time. Working under the extreme urgency of diminishing hours available for life-saving rescue of victims, the international teams acknowledged separately the damaging consequences of conflicting technologies and inadequate administrative coordination. The working environment of the international teams, however, was further constrained by the detrimental effects of national concerns for reputation. Pride and commitment to specific technologies by separate national teams tended to obstruct the genuine exploration of cooperative solutions to the extremely difficult problems of search and rescue midst the urban mountains of collapsed concrete and steel. The criterion of fit performance, nonetheless, remained the successful rescue of live victims. The low ratio of victims
found to effort expended compelled all participating teams to reflect soberly upon their collective performance.

An emerging adaptive system is identifiable in the context of these interactions. The structures are the nine international search and rescue teams, operating independently and in conjunction with assigned departments of the Mexican government. The operators influencing these structures are the means of communication, informal among colleagues between the national embassies in Mexico City, more formal among scheduled meetings with representatives of the national embassies and international organizations (UNDRO, PAHO), more importantly, interpersonal communication among members of different international teams sharing common tasks. The inputs to this system are the reports in the media, particularly the international press, which allowed members of the different national teams to learn how others perceived their actions in contrast to their own intent.

Tentative, incomplete, a beginning adaptive plan is recognizable in the spontaneous actions among several of the international teams. For example, representatives of the U.S., German and Swiss dog teams began meeting each evening to share information from the day's activities, to learn of new sites for the possible location of survivors and to coordinate, jointly, their activities for the following day. In another instance, representatives from a Japanese team of structural engineers, visiting the sites of the collapsed buildings and investigating the effects of the magnitude and intensity of the earthquake upon
different structural forms, filmed a videotape to record their assessments and shared this tape with members of the U.S. team.58 Cooperative inquiry of this kind contributes to the cumulation of international data regarding the effects of massive earthquakes in urban settings. Actions such as these, evolving out of the common recognition of the need for better coordination among search and rescue teams and better information about the structural design of buildings being searched, demonstrate the shared commitment of the participating teams to the collective goal of rescue of the victims.

Towards the Formation of Professional Standards for International Search and Rescue Operations

Engagement in the international search and rescue process precipitated differing responses from individual teams, but the experience engendered thoughtful reflection on the requirements for improved performance in international disaster assistance and generated fresh commitment to design a set of professional standards in search and rescue operations. The handlers of search dogs with the U.S. team, for example, have developed, at the request of the then U.S. Ambassador to Mexico, John Gavin, an organizational format and set of operational procedures to mobilize an official U.S. Dog Team for search and rescue operations in any disaster, national or international.59 Other conferences, national and international, have focused on the experience of search and rescue operations in the Mexico City disaster and have generated a continuing inquiry into the design
of an effective process for international disaster assistance, drawing constructively upon the lessons learned in the Mexican experience. These efforts are tentative, nascent steps in the direction of improved performance in international disaster assistance. They are still in process and have yet to be tested in actual performance. Yet these efforts do indicate the powerful capacity of individual participants to select from their own performance in actual situations those qualities that demonstrate 'fitness' to the complex environment of disaster operations and to discard those that prove ineffective or irrelevant.

The Perception of International Disaster Assistance by the Affected Mexican Population

An important test of the model of adaptation in the international disaster assistance process in the Mexican disaster is the perception of that process by the intended beneficiaries, the residents of the damaged areas in Mexico City. A survey of 728 residents of these areas reveals some interesting findings in reference to their actual experience with international disaster assistance. The findings provide a useful check against the reported operation of the process as perceived by the press, members of the international teams and the governments they served. Especially interesting was a series of questions that appear to show a direct relationship between involvement in international disaster assistance and information available. These findings are reported in Tables 1-5.
As cited in Table 1, the large majority, 563 out of 728 respondents (77.3%) in the survey, perceived international aid to be very beneficial or beneficial to Mexico in coping with the problems generated by the earthquakes. Yet, when asked whether there was information in their district about how to get access to this international aid, the proportion responding positively dropped to 258, or 35.4%, of the respondents in the survey. When asked whether the information given in their district about how to ask for, and receive, aid was sufficient, the proportion responding positively dropped still further to 167 respondents, or 22.9% of the total number interviewed. The number of respondents who reported actually receiving aid, either themselves, their families or their immediate neighbors dropped again to 76 residents, or 10.4% of the total sample. Those who reported actual contact with an international organization engaged in disaster assistance, either themselves, their families or their neighbors, fell to the very small proportion of 47 respondents, or 6.5% of the total number of cases in the sample.

These findings indicate that, although the large majority of residents of the damaged neighborhoods in Mexico City were aware of the international assistance being given to Mexico and perceived it positively, very few residents actually received such assistance and even fewer had contact with international organizations engaged in the delivery of such assistance. Given the complexity of the environment, the ratio of assistance received to assistance extended is not surprising. What appears

</table>
to be critical, however, is the level of information available to citizens to initiate their own actions to request and receive international disaster assistance.

Further analysis indicates that even those who did receive aid or had contact with international organizations did not always report that information about international aid was either available in their district or sufficient to gain access. Table 6 shows that of the 252 respondents who reported that information regarding international aid was available in their districts, more than one-third, 36.9%, found that information to be insufficient in order to request or receive aid. Table 7 cites that of the 75 respondents who reported actually receiving international aid, 28, or 37.3% stated there was no information about aid in their district. More telling, nearly two-thirds of the respondents, 65.8%, reported they did not receive international aid and that information about international aid was not available in their districts. In Table 8, 23 of the 54 respondents, 42.6%, who reported receiving international aid perceived information about aid to be insufficient. It is also interesting that 22 of the 76 respondents who reported receiving aid (28.9%) did not respond to the question on sufficiency of information.

Relating these findings to the operation of the international disaster assistance process, it is clear that there are major discrepancies between the intent and effort expended and the actual receipt of international assistance by residents
of the damaged neighborhoods. While there is evidence of adaptation occurring among the participating international organizations for the mobilization and dispatch of assistance to the disaster environment, that process is not yet complementary to the requirements for requesting and receiving aid by the neighborhood residents. Yet, in contrast to the theory of organizational anarchy in complex environments where organizations are perceived as making decisions only by chance\(^6\), data from the international disaster assistance process in the Mexican case show an evolving capacity by the international system to modify its form of operations in a disaster environment based upon a clear criterion of fit performance, specifically the

rescue of human life. An adaptive plan, rather than chance, appears to be influencing decisions made by participants in the international search and rescue process.

Extending this adaptive plan to the larger environment of the intended recipients of international disaster assistance is a still more complex and difficult task. The most promising means appears to be through increasing the level of information available to the intended recipients, so that they may also add their energy and capacity to the evolving adaptive system.
Notes

Many people contributed time, effort and knowledge to facilitate the research on which this article is based. I wish to thank, in particular, Fernando Estrada, Federico Estevez, Rosario Molinero, Timothy Broughton, Samuel Taylor, Paul Bell, Lee Johnson, Harry Iceland, George Natanson and Victoria Funari, who assisted me in the conduct of this research in Mexico City. I also thank Joyce Valiquette, Jan Jernigan, Maria Klyver, Richard Greene and Marcel Dennert for their assistance at the University of Pittsburgh.
